- Algorithm for Computing the Optimal Costs
  - MATRIX-CHAIN-ORDER
- Construction and Optimal Solution
  - MATRIX-CHAIN-MULTIPLY
- Summary

### **Dynamic Programming - Introduction**

- An algorithm design paradigm like divide-and-conquer
- Programming: A tabular method (not writing computer code)
  - Older sense of planning or scheduling, typically by filling in a table
- Divide-and-Conquer (DAC): subproblems are independent
- Dynamic Programming (DP): subproblems are not independent
- Overlapping subproblems: subproblems share sub-subproblems
  - In solving problems with overlapping subproblems
    - A DAC algorithm does redundant work
      - Repeatedly solves common subproblems
    - A DP algorithm solves each problem just once
      - Saves its result in a table

## Problem 1: Fibonacci Numbers Recursive Solution

#### • Reminder:

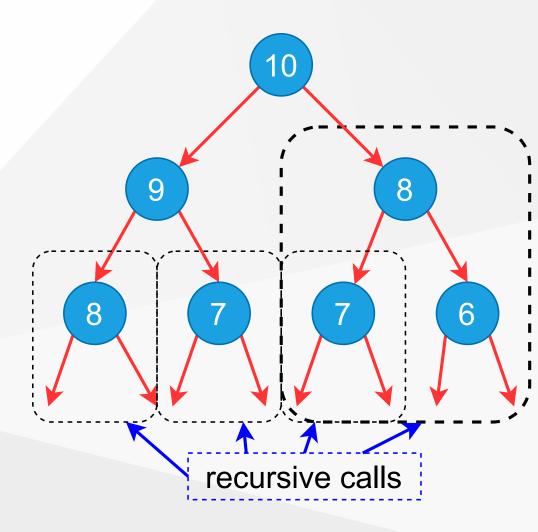

else

CE100 Week-5

$$F(0) = 0$$
 and  $F(1) = 1$ 
 $F(n) = F(n-1) + F(n-2)$ 
 $ext{REC-FIBO}(n)\{$ 
 $ext{if } n < 2$ 
 $ext{return } n$ 

return REC-FIBO(n-1) + REC-FIBO(n-2) }

 Overlapping subproblems in different recursive calls. Repeated work!

#### **Problem 1: Fibonacci Numbers Recursive Solution**

- Recurrence:
  - exponential runtime

$$T(n) = T(n-1) + T(n-2) + 1$$

• Recursive algorithm inefficient because it recomputes the same F(i) repeatedly in different branches of the recursion tree.

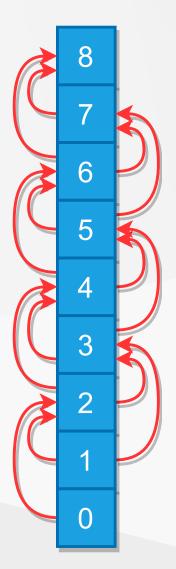

# Problem 1: Fibonacci Numbers Bottom-up Computation

• Reminder:

$$F(0) = 0 \text{ and } F(1) = 1$$
  
 $F(n) = F(n-1) + F(n-2)$ 

• Runtime  $\Theta(n)$ 

```
ITER-FIBO(n)
  F[0] = 0
  F[1] = 1
  for i = 2 to n do
    F[i] = F[i-1] + F[i-2]
  return F[n]
```

### **Optimization Problems**

- **DP** typically applied to optimization problems
- In an optimization problem
  - There are many possible solutions (feasible solutions)
  - Each solution has a value
  - Want to find an optimal solution to the problem
    - A solution with the optimal value (min or max value)
  - Wrong to say the optimal solution to the problem
    - There may be several solutions with the same optimal value

## Development of a DP Algorithm

- Step-1. Characterize the structure of an optimal solution
- Step-2. Recursively define the value of an optimal solution
- Step-3. Compute the value of an optimal solution in a bottom-up fashion
- Step-4. Construct an optimal solution from the information computed in Step 3

#### **Problem 2: Matric Chain Multiplication**

- Input: a sequence (chain)  $\langle A_1, A_2, \ldots, A_n 
  angle$  of n matrices
- Aim: compute the product  $A_1 \cdot A_2 \cdot \ldots A_n$
- A product of matrices is fully parenthesized if
  - It is either a **single matrix**
  - Or, the product of two fully parenthesized matrix products surrounded by a pair of parentheses.

$$egin{aligned} igg(A_i(A_{i+1}A_{i+2}\dots A_j)igg) \ igg((A_iA_{i+1}A_{i+2}\dots A_{j-1})A_jigg) \ igg((A_iA_{i+1}A_{i+2}\dots A_k)(A_{k+1}A_{k+2}\dots A_j)igg) ext{ for } i\leq k < j \end{aligned}$$

• All parenthesizations yield the same product; matrix product is associative

#### Matrix-chain Multiplication: An Example Parenthesization

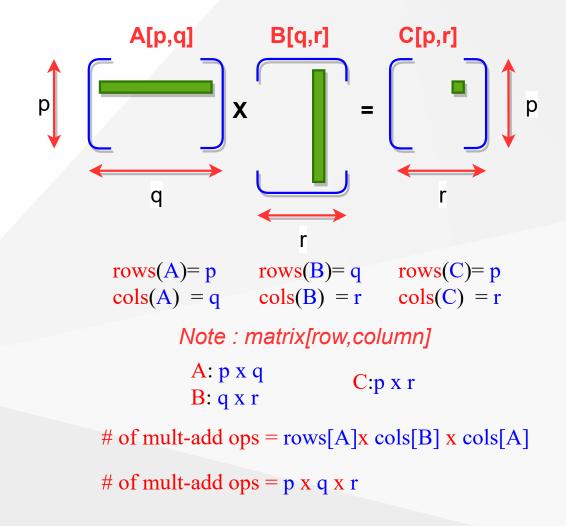

• Input:  $\langle A_1, A_2, A_3, A_4 \rangle$  (5 distinct ways of full parenthesization)

$$\begin{pmatrix} A_1 \left( A_2 (A_3 A_4) \right) \\ \left( A_1 \left( (A_2 A_3) A_4 \right) \right) \\ \left( (A_1 A_2) (A_3 A_4) \right) \\ \left( \left( A_1 (A_2 A_3) A_4 \right) \right) \\ \left( \left( (A_1 A_2) A_3 \right) A_4 \right) \\ \end{pmatrix}$$

• The way we parenthesize a chain of matrices can have a dramatic effect on the cost of computing the product

## Matrix-chain Multiplication: Reminder

```
MATRIX-MULTIPLY(A, B)
  if cols[A]!=rows[B] then
    error("incompatible dimensions")
  for i=1 to rows[A] do
    for j=1 to cols[B] do
        C[i,j]=0
        for k=1 to cols[A] do
        C[i,j]=C[i,j]+A[i,k]·B[k,j]
    return C
```

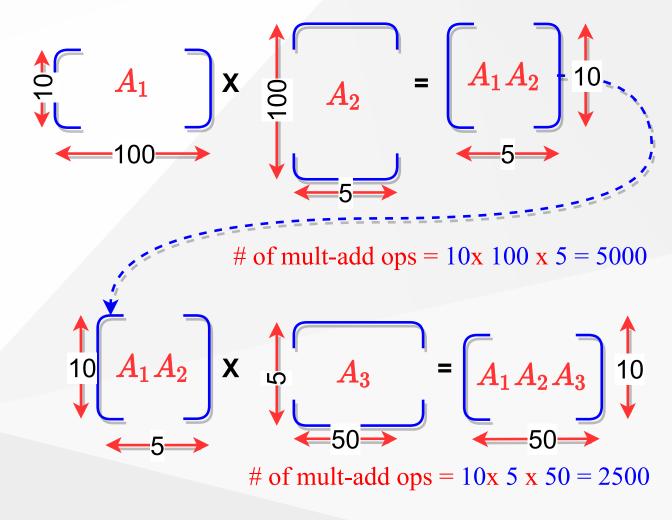

# Matrix Chain Multiplication: Example

• A1:10x100, A2:100x5,

A3:5x50

 $\circ$  Which paranthesization is better? (A1A2)A3 or A1(A2A3)?

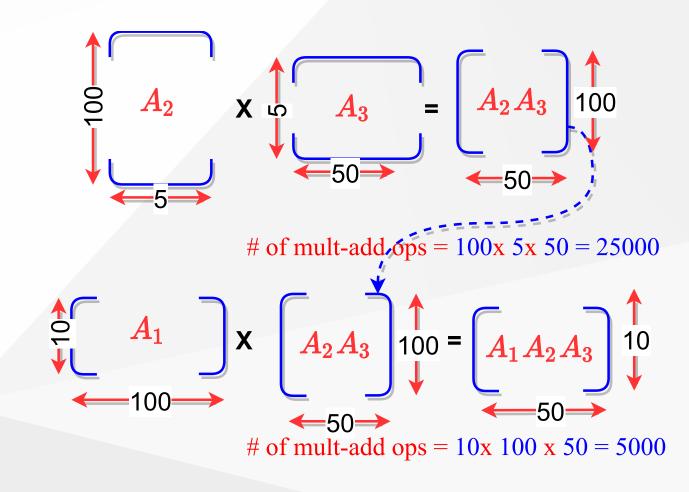

# of mult-add ops = 5000+2500 = 7500

# Matrix Chain Multiplication: Example

- ullet A1:10 imes100, A2:100 imes5, A3:5 imes50
  - $\circ$  Which paranthesization is better? (A1A2)A3 or A1(A2A3)?

# of mult-add ops = 25000+5000 = 75000

#### Matrix Chain Multiplication: Example

- ullet A1:10 imes100, A2:100 imes5, A3:5 imes50
  - $\circ$  Which paranthesization is better? (A1A2)A3 or A1(A2A3)?

#### In summary:

- (A1A2)A3 = # of multiply-add ops: 7500
- A1(A2A3) = # of multiple-add ops: 75000

First parenthesization yields 10x faster computation

#### Matrix-chain Multiplication Problem

- Input: A chain  $\langle A_1, A_2, \ldots, A_n \rangle$  of n matrices,
  - $\circ$  where  $A_i$  is a  $p_{i-1} imes p_i$  matrix
- Objective: Fully parenthesize the product
  - $\circ A_1 \cdot A_2 \dots A_n$ 
    - such that the number of scalar mult-adds is minimized.

#### **Counting the Number of Parenthesizations**

- Brute force approach: exhaustively check all parenthesizations
- P(n): # of parenthesizations of a sequence of n matrices
- We can split sequence between  $k^{th}$  and  $(k+1)^{st}$  matrices for any  $k=1,2,\ldots,n-1$ , then parenthesize the two resulting sequences independently, i.e.,

$$(A_1A_2A_3\dots A_k) (A_{k+1}A_{k+2}\dots A_n)$$

We obtain the recurrence

$$P(1) = 1 \text{ and } P(n) = \sum_{k=1}^{n-1} P(k)P(n-k)$$

#### **Number of Parenthesizations:**

$$ullet P(1)=1$$
 and  $P(n)=\sum\limits_{k=1}^{n-1}P(k)P(n-k)$ 

ullet The recurrence generates the sequence of **Catalan Numbers** Solution is P(n)=C(n-1) where

$$C(n)=rac{1}{n+1}inom{2n}{n}=\Omega(4^n/n^{3/2})$$

- ullet The number of solutions is **exponential** in n
- Therefore, brute force approach is a poor strategy

### The Structure of Optimal Parenthesization

- Notation:  $A_{i...j}$ : The matrix that results from evaluation of the product:  $A_iA_{i+1}A_{i+2}\ldots A_j$
- Observation: Consider the last multiplication operation in any parenthesization:  $(A_1A_2\ldots A_k)\cdot (A_{k+1}A_{k+2}\ldots A_n)$ 
  - $\circ$  There is a k value  $(1 \le k < n)$  such that:
    - lacktriangle First, the product  $A_1 \dots k$  is computed
    - lacktriangle Then, the product  $A_{k+1\ldots n}$  is computed
    - lacktriangle Finally, the matrices  $A_{1\ldots k}$  and  $A_{k+1\ldots n}$  are multiplied

### **Step 1: Characterize the Structure of an Optimal Solution**

- An optimal parenthesization of product  $A_1A_2\dots A_n$  will be:  $(A_1A_2\dots A_k)\cdot (A_{k+1}A_{k+2}\dots A_n)$  for some k value
- The cost of this optimal parenthesization will be:
  - = Cost of computing  $A_{1...k}$
  - + Cost of computing  $A_{k+1\ldots n}$
  - + Cost of multiplying  $A_{1\ldots k}\cdot A_{k+1\ldots n}$

## **Step 1: Characterize the Structure of an Optimal Solution**

• Key observation: Given optimal parenthesization

$$\circ \ (A_1A_2A_3\ldots A_k)\cdot (A_{k+1}A_{k+2}\ldots A_n)$$

- ullet Parenthesization of the subchain  $A_1A_2A_3\ldots A_k$
- Parenthesization of the subchain  $A_{k+1}A_{k+2}\ldots A_n$

#### should both be optimal

- Thus, optimal solution to an instance of the problem contains optimal solutions to subproblem instances
  - o i.e., optimal substructure within an optimal solution exists.

- Step 2: Define the value of an optimal solution recursively in terms of optimal solutions to the subproblems
- ullet Assume we are trying to determine the min cost of computing  $A_{i\ldots j}$
- ullet  $m_{i,j}$ : min # of scalar multiply-add opns needed to compute  $A_{i\ldots j}$ 
  - $\circ$  **Note**: The optimal cost of the original problem:  $m_{1,n}$
- How to compute  $m_{i,j}$  recursively?

- ullet Base case:  $m_{i,i}=0$  (single matrix, no multiplication)
- ullet Let the size of matrix  $A_i$  be  $(p_{i-1} imes p_i)$
- Consider an optimal parenthesization of chain

$$\circ \ A_i \ldots A_j : (A_i \ldots A_k) \cdot (A_{k+1} \ldots A_j)$$

- ullet The optimal cost:  $m_{i,j} = m_{i,k} + m_{k+1,j} + p_{i-1} imes p_k imes p_j$
- where:
  - $\circ \; m_{i,k}$ : Optimal cost of computing  $A_{i\ldots k}$
  - $\circ \ m_{k+1,j}$ : Optimal cost of computing  $A_{k+1\ldots j}$
  - $\circ~p_{i-1} imes p_k imes p_j$  : Cost of multiplying  $A_{i\dots k}$  and  $A_{k+1\dots j}$

- ullet In an optimal parenthesization: k must be chosen to minimize  $m_{ij}$
- The recursive formulation for  $m_{ij}$ :

$$m_{ij} = egin{cases} 0 & if \ i = j \ MIN\{m_{ik} + m_{k+1,j} + p_{i-1}p_kp_j\} & if \ i < j \end{cases}$$

- ullet The  $m_{ij}$  values give the **costs of optimal solutions** to subproblems
- In order to keep track of how to construct an optimal solution
  - $\circ$  Define  $s_{ij}$  to be the value of k which yields the optimal split of the subchain  $A_{i\ldots j}$ 
    - lacksquare That is,  $s_{ij}=k$  such that
      - $lacksquare m_{ij} = m_{ik} + m_{k+1,j} + p_{i-1}p_kp_j$  holds

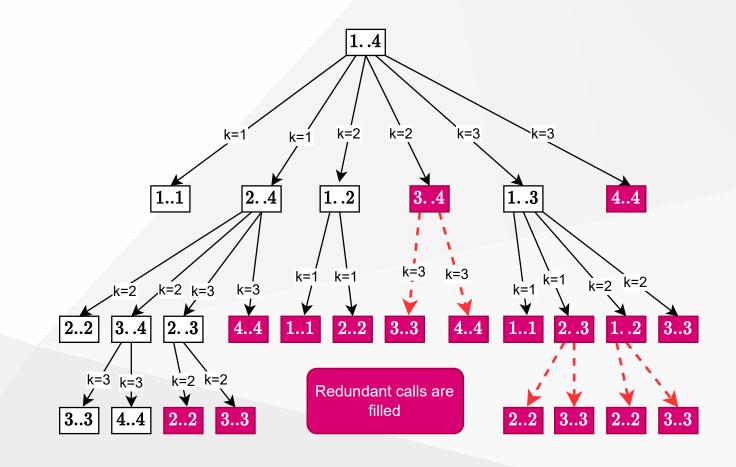

#### **Direct Recursion: Inefficient!**

• Recursive Matrix-Chain (RMC) Order

```
RMC(p,i,j)
 if (i == j) then
    return 0
 m[i, j] = INF
  for k=i to j-1 do
    q = RMC(p, i, k) + RMC(p, k+1, j) + p_{i-1} p_k p_j
    if q < m[i, j] then</pre>
      m[i, j] = q
  endfor
        return m[i, j]
```

# Direct Recursion: Inefficient!

- ullet Recursion tree for RMC(p,1,4)
- ullet Nodes are labeled with i and j values

#### Computing the Optimal Cost (Matrix-Chain Multiplication)

#### An important observation:

- We have relatively few subproblems
  - $\circ$  one problem for each choice of i and j satisfying  $1 \leq i \leq j \leq n$
  - $\circ$  total  $n+(n-1)+\cdots+2+1=rac{1}{2}n(n+1)=\Theta(n2)$  subproblems
- We can write a **recursive** algorithm based on recurrence.
- However, a recursive algorithm may encounter each subproblem many times in different branches of the recursion tree
- This property, overlapping subproblems, is the second important feature for applicability of dynamic programming

## Computing the Optimal Cost (Matrix-Chain Multiplication)

- Compute the value of an optimal solution in a bottom-up fashion
  - $\circ$  matrix  $A_i$  has dimensions  $p_{i-1} imes p_i$  for  $i=1,2,\ldots,n$
  - $\circ$  the input is a sequence  $\langle p_0, p_1, \dots, p_n 
    angle$  where length[p] = n+1
- Procedure uses the following auxiliary tables:
  - $\circ \ m[1\ldots n,1\ldots n]$ : for storing the m[i,j] costs
  - $\circ \ s[1\dots n,1\dots n]$ : records which index of k achieved the optimal cost in computing m[i,j]

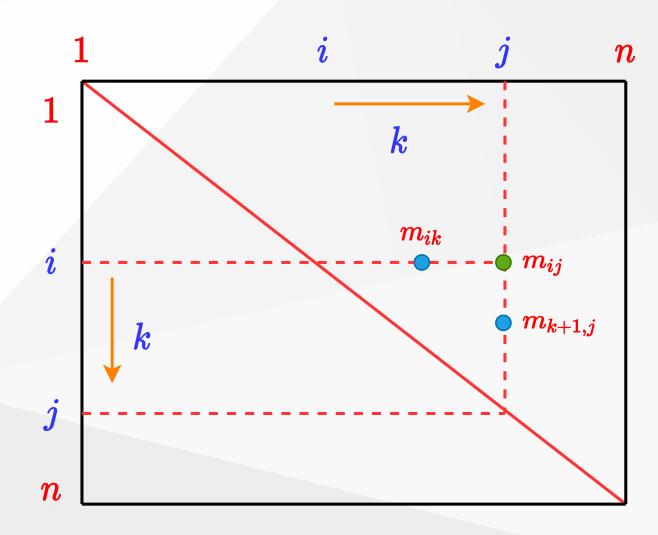

- How to choose the order in which we process  $m_{ij}$  values?
- Before computing  $m_{ij}$ , we have to make sure that the values for  $m_{ik}$  and  $m_{k+1,j}$  have been computed for all k.

$$m_{ij} = \mathop{MIN}\limits_{i \leq k < j} \{m_{ik} + m_{k+1,j} + p_{i-1}p_kp_j\}$$

$$m_{ij} = \mathop{MIN}\limits_{i \leq k < j} \{m_{ik} + m_{k+1,j} + p_{i-1}p_kp_j\}$$

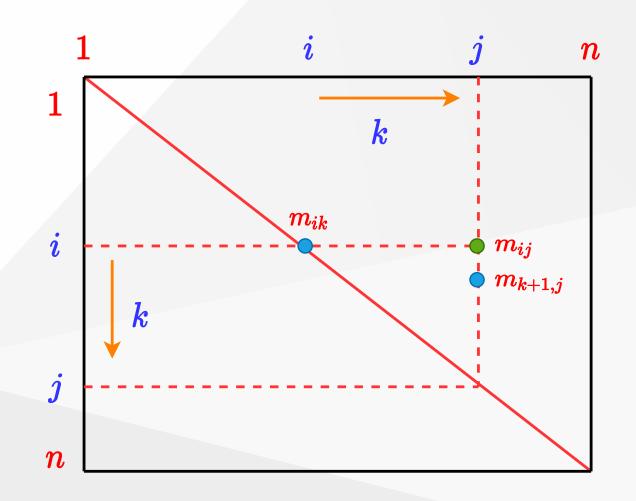

- $ullet m_{ij}$  must be processed after  $m_{ik}$  and  $m_{j,k+1}$
- ullet Reminder:  $m_{ij}$  computed only for j>i

$$m_{ij} = \mathop{MIN}\limits_{i \leq k < j} \{m_{ik} + m_{k+1,j} + p_{i-1}p_kp_j\}$$

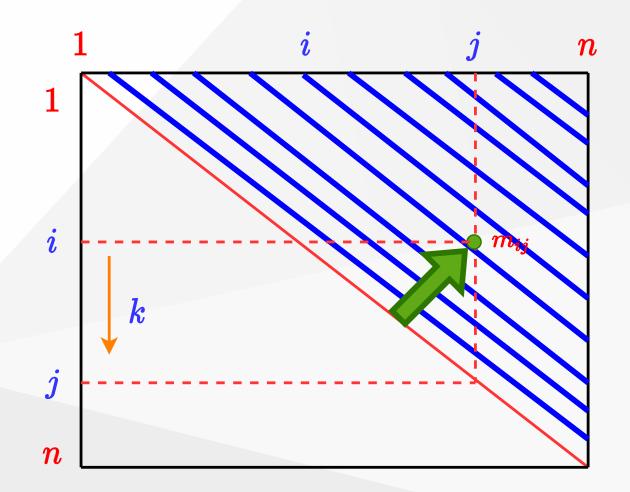

- $ullet m_{ij}$  must be processed after  $m_{ik}$  and  $m_{j,k+1}$
- How to set up the iterations over i and j to compute  $m_{ij}$ ?

$$m_{ij} = \mathop{MIN}\limits_{i \leq k < j} \{m_{ik} + m_{k+1,j} + p_{i-1}p_kp_j\}$$

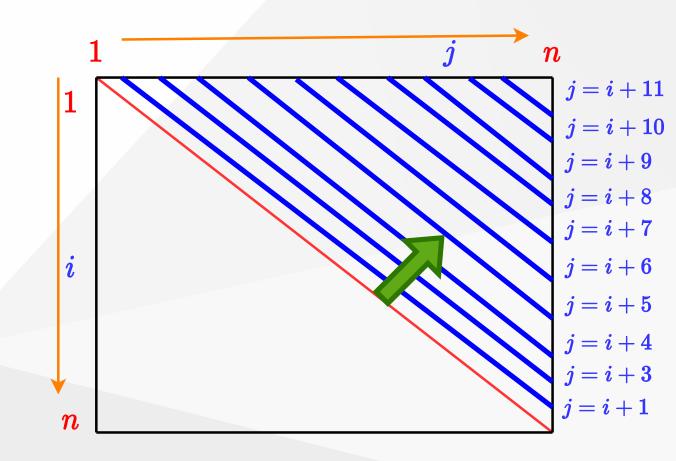

• If the entries  $m_{ij}$  are computed in the shown order, then  $m_{ik}$  and  $m_{k+1,j}$  values are guaranteed to be computed before  $m_{ij}$ .

# **Bottom-Up Computation**

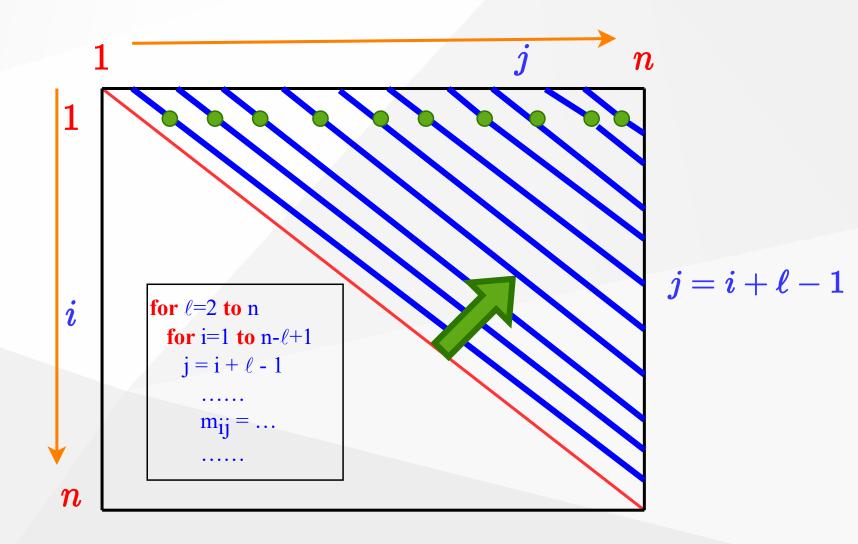

$$m_{ij} = \mathop{MIN}\limits_{i \leq k < j} \{m_{ik} + m_{k+1,j} + p_{i-1}p_kp_j\}$$

# Bottom-Up Computation

$$m_{ij} = \mathop{MIN}\limits_{i \leq k < j} \{m_{ik} + m_{k+1,j} + p_{i-1}p_kp_j\}$$

#### Algorithm for Computing the Optimal Costs

ullet Note: I  $=\ell$  and p\_{i-1}p\_k p\_j  $=p_{i-1}p_k p_j$ 

```
MATRIX-CHAIN-ORDER(p)
  n = length[p]-1
  for i=1 to n do
    m[i, i] = 0
  endfor
  for l=2 to n do
    for i=1 to n n-l+1 do
      j=i+l-1
      m[i, j]=INF
      for k=i to j-1 do
        q=m[i,k]+m[k+1, j]+p_{i-1} p_k p_j
        if q < m[i,j] then</pre>
          m[i,j]=q
          s[i,j]=k
      endfor
    endfor
  endfor
  return m and s
```

# Algorithm for Computing the Optimal Costs

- The algorithm first computes
  - $\circ \ m[i,i] \leftarrow 0$  for  $i=1,2,\ldots,n$  min costs for all chains of length 1
- ullet Then, for  $\ell=2,3,\ldots,n$  computes
  - $\circ \ m[i,i+\ell-1]$  for  $i=1,\ldots,n-\ell+1$  min costs for all chains of length  $\ell$
- ullet For each value of  $\ell=2,3,\ldots,n$ ,
  - $m[i,i+\ell-1]$  depends only on table entries  $m[i,k]\&m[k+1,i+\ell-1]$  for  $i\leq k < i+\ell-1$ , which are already computed

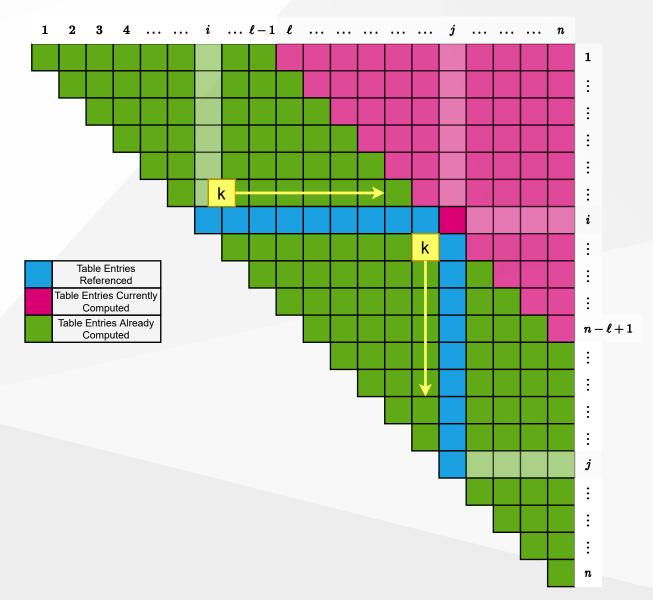

# Algorithm for Computing the Optimal Costs

- $((A_1)(A_2A_3))((A_4A_5)(A_6))$ 
  - $\circ$  What is the optimal split for  $A_2A_3$  ? (  $s_{23}=2$  )
  - $\circ$  What is the optimal split for  $A_4A_5$  ? (  $s_{45}=4$  )

ullet Reminder:  $s_{ij}$  is the optimal top-level split of  $A_i \dots A_j$ 

- $\circ$  What is the optimal split for  $A_2A_3$  ? (  $s_{23}=2$  )
- $\circ$  What is the optimal split for  $A_4A_5$  ? (  $s_{45}=4$  )

#### **Constructing an Optimal Solution**

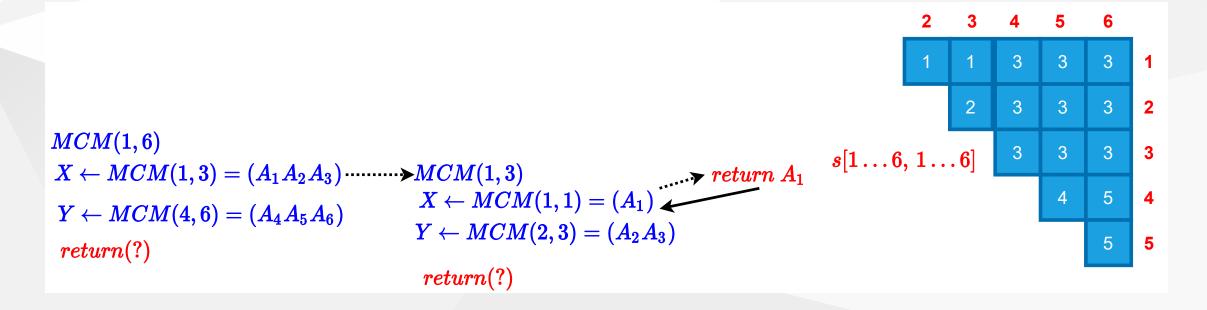

- Earlier optimal matrix multiplications can be computed recursively
- Given:
  - $\circ$  the chain of matrices  $A=\langle A_1,A_2,\ldots A_n
    angle$  the s table computed by MATRIX-CHAIN-ORDER
  - $\circ$  The following recursive procedure computes the matrix-chain product  $A_{i\ldots j}$

```
\operatorname{MATRIX-CHAIN-MULTIPLY}(A,s,i,j) if j>i then X \longleftarrow \operatorname{MATRIX-CHAIN-MULTIPLY}(A,s,i,s[i,j]) Y \longleftarrow \operatorname{MATRIX-CHAIN-MULTIPLY}(A,s,s[i,j]+1,j) return \operatorname{MATRIX-MULTIPLY}(X,Y) else \operatorname{return} A_i
```

• Invocation: MATRIX-CHAIN-MULTIPLY (A, s, 1, n)

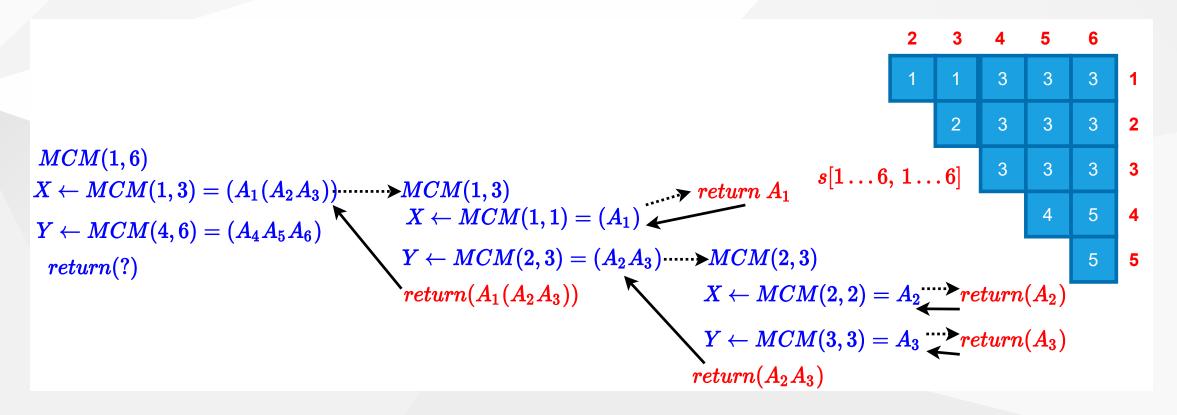

# **Example: Recursive Construction of an Optimal Solution**

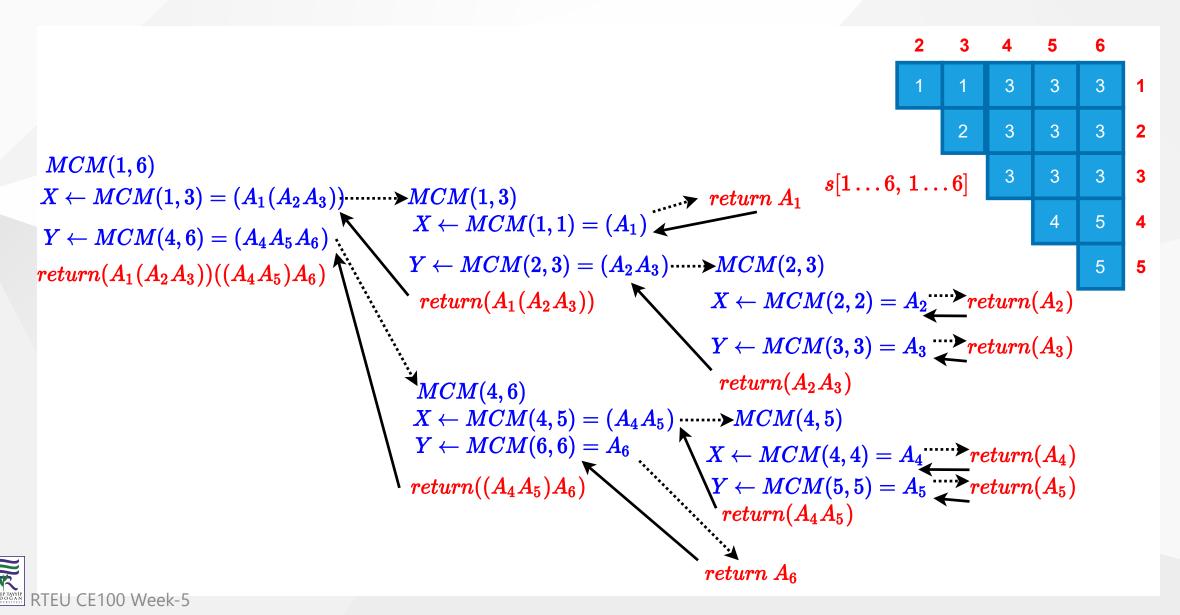

# **Example: Recursive Construction of an Optimal Solution**

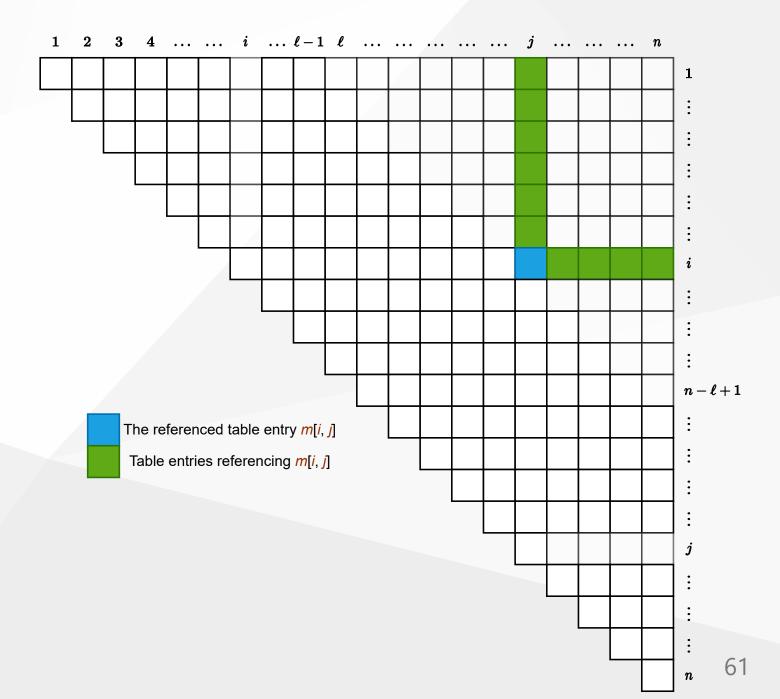

## **Example: Recursive Construction of an Optimal Solution**

# Table reference pattern for m[i,j]

$$(1 \le i \le j \le n)$$

- m[i,j] is referenced for the computation of
  - $m[i,r] ext{ for } j < 0$   $r \leq n \ (n-j)$  times
  - $egin{aligned} \circ & m[r,j] ext{ for } 1 \leq \ & r < i \ (i-1) \ & ext{times} \end{aligned}$

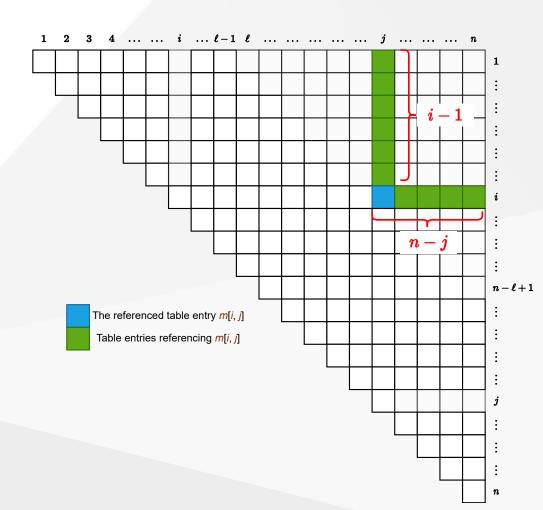

# Table reference pattern for m[i,j] $(1 \leq i \leq j \leq n)$

• R(i,j) = # of times that m[i,j] is referenced in computing other entries

$$R(i,j) = (n-j) + (i-1)$$
  
=  $(n-1) - (j-i)$ 

• The total # of references for the entire table is:  $\sum_{i=1}^n \sum_{j=i}^n R(i,j) = \frac{n^3-n}{3}$ 

# **Summary**

- Identification of the optimal substructure property
- Recursive formulation to compute the cost of the optimal solution
- Bottom-up computation of the table entries
- Constructing the optimal solution by backtracing the table entries
